## Getting Started

Before you get started, you'll need to gather a few supplies. These include:

- A computer or laptop
- An internet connection
- A text editor (such as Notepad or TextEdit)
- A web browser (such as Chrome or Firefox)

Once you have your supplies, you're ready to get started. The first step is to create a new text file. You can do this by opening your text editor and clicking on "File" > "New".

Once you have created a new text file, you need to save it. Click on "File" > "Save" and choose a location to save the file. You should also give the file a name. For example, you could name the file "my\_first\_program.txt".

## **Writing Your First Program**

Now that you have created a new text file, you can start writing your first program. A program is simply a set of instructions that tells the computer what to do. Programs are written in a programming language, which is a special language that computers can understand.

For this guide, we will be using the Python programming language. Python is a popular programming language that is easy to learn and use. To write a Python program, you simply need to type the Python code into a text editor.

Here is a simple Python program that prints the words "Hello, world!" to the screen:

```
python print("Hello, world!")
```

To run this program, you need to open a terminal window and type the following command:

```
python my_first_program.txt
```

This will run the Python program and print the words "Hello, world!" to the terminal window.

## **Variables**

Variables are used to store data in a program. You can think of a variable as a box that can hold a value. To create a variable, you simply need to assign it a value. For example, the following code creates a variable called "name" and assigns it the value "John":

```
python name ="John"
```

You can use the print() function to print the value of a variable. For example, the following code prints the value of the "name" variable:

```
python print(name)
```

This will print the word "John" to the terminal window.

## **Operators**

Operators are used to perform operations on data. For example, the addition operator (+) is used to add two numbers together. The following code adds the numbers 1 and 2 together and stores the result in the "sum" variable:

```
python sum = 1 + 2
```

You can use the print() function to print the value of the "sum" variable:

```
python print(sum)
```

This will print the number 3 to the terminal window.

## Control Flow

Control flow statements are used to control the flow of execution in a program. For example, the if statement is used to execute a block of code only if a certain condition is met. The following code uses the if statement to print the word "Hello" if the "name" variable is equal to "John":

```
python if name == "John": print("Hello")
```

You can use the else statement to execute a block of code if the condition in the if statement is not met. The following code uses the else statement to print the word "Goodbye" if the "name" variable is not equal to "John":

```
python if name == "John": print("Hello") else: print("Goodbye")
```

The elif statement can be used to check for multiple conditions. The following code uses the elif statement to
